(54) Ultrasonic atomizing device.

(57) An ultrasonic device for atomizing a liquid by the acoustic vibration generated with a vibrating plate (2) being mounted to a piezoelectric vibrator (1). The piezoelectric vibrator (1) consists of a piezoelectric ceramic and a pair of electrodes (P,Q) on the both end surfaces perpendicular to the thickness direction of the piezoelectric ceramic (30). The vibrating plate (2) has a lot of holes (22), and the area of the one of the openings of the hole is different with the area of

the other. The piezoelectric vibrator (1) is efficiently vibrated under an application of an alternating current signal, whose frequency is almost equal to the resonance frequency of the piezoelectric vibrator (1). This vibration is transmitted to the vibrating plate (2), so that the vibrating plate (2) is also vibrated. A liquid existing at the part of the vibrating plate (2) is atomized through a lot of holes (22) formed in the vibrating plate (2).

FIG. 1

FIG. 21

EP 0 480 615 A1

The present invention relates to an ultrasonic device for atomizing a liquid by the acoustic vibration generated with an ultrasonic vibrator.

As conventional atomizing devices, a device using a Langevin-type vibrator with a bolt and Neblizer are known. The device composed of the Langevin-type vibrator with a bolt operating a frequency of some 10 kHz has a merit of generating a large quantity of fog, while the structure is complicated and the size is large. The Neblizer employing the ultrasonic vibration with the frequency of MHz is regarded as a useful atomizer for minute and uniform particle. However, it has the defect of a little quantity of fog with a low electric power because of a low atomization efficiency. In other words, those conventional devices have more than one weak point from the viewpoints of atomization efficiency, atomization ability, the minuteness of the particle, or running cost with power supply for operation.

SUMMARY OF THE INVENTION

An object of the present invention is to provide an atomizing device having a high efficiency of atomization under low electric power supply.

Another object of the present invention is to provide an atomizing device capable of providing a large quantity of fog.

Other object of the present invention is to provide an atomizing device available for the minuteness and the uniformity of fog particle.

Still other object of the present invention is to provide an atomizing device with a small size which is very light in weight and has a simple structure.

Still further object of the present invention is to provide an atomizing device operating under low power consumption.

According to one aspect of the present invention there is provided an atomizing device comprising an ultrasonic vibrator, which generates an acoustic vibration to atomize a liquid and is composed of a piezoelectric vibrator and a vibrating plate.

According to another aspect of the present invention there is provided a means for supplying the vibrating plate with the liquid.

According to other aspect of the present invention there is provided a piezoelectric vibrator composed of a piezoelectric ceramic and a pair of electrodes on the both end surfaces perpendicular to the thickness direction of the piezoelectric ceramic.

According to further aspect of the present invention there is provided a vibrating plate having a lot of holes, and the area of the one of the openings of the hole is different from the area of the

other.

Other features and advantages of the invention will be clarified from the following description with reference to the attached drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a sectional view of the ultrasonic atomizing device according to the present invention showing the first embodiment.

FIG. 2 shows a sectional view of the first embodiment shown in FIG. 1 excepting the liquid supplying tube 5, the flow control valve 6 and the liquid tank 7.

FIG. 3 shows a perspective view of the clip 4 seen in FIG. 1.

FIG. 4 shows a side view of the clip 4 shown in FIG. 3.

FIG. 5 shows a plan view of the ultrasonic vibrator (that is the device composed of the piezoelectric vibrator 1 and the vibrating plate 2) seen in FIG. 1.

FIG. 6 shows a fragmentary top plan view, on an enlarged scale, of a portion of the vibrating part 20 seen in FIG. 5.

FIG. 7 shows a side view of the ultrasonic vibrator shown in FIG. 5.

FIG. 8 shows a fragmentary vertical sectional view, on an enlarged scale, of a portion of the vibrating part 20 seen in FIG. 5.

FIG. 9 shows the frequency dependences of the magnitude and the phase of the admittance of the piezoelectric vibrator 1.

FIG. 10 shows the relationship between the atomizing quantity and the applied voltage for the first embodiment.

FIG. 11 shows the relationship between the atomizing height and the atomizing distance for various applied voltages for the first embodiment.

FIG. 12 shows a plan view of the ultrasonic vibrator taking the place of that shown in FIG. 5.

FIG. 13 shows the relationship between the length of the vibrating part 20 and the atomizing quantity for the ultrasonic vibrator shown in FIG. 12.

FIG. 14 shows the relationship between the length of the vibrating part 20 shown in FIG. 12 and the atomizing height.

FIG. 15 shows the relationship between the phase of the impedance of the piezoelectric vibrator 1 seen in FIG. 12 and the frequency.

FIG. 16 shows the relationship between the phase of the impedance of the ultrasonic vibrator shown in FIG. 12 and the frequency.

FIG. 17(A) shows a perspective view of the ultrasonic vibrator taking the place of that shown in FIG. 5.

FIG. 17(B) shows a perspective view of the

ultrasonic vibrator taking the place of that shown in FIG. 17(A).

FIG. 18 shows a sectional view of the ultrasonic atomizing device, showing the second embodiment, excluding the liquid supplying tube 5, the flow control valve 6 and the liquid tank 7 from the first embodiment shown in FIG. 1 and including the liquid bath 8 in the first embodiment in FIG. 1.

FIG. 19 shows a sectional view of the ultrasonic atomizing device, showing the third embodiment, excluding the supporter 3 and the clip 4 from the first embodiment shown in FIG. 1 and setting the liquid supplying tube 5 upward the vibrating plate 2.

FIG. 20 shows a sectional view of the ultrasonic atomizing device according to the present invention showing the fourth embodiment.

FIG. 21 shows a sectional view of the ultrasonic atomizing device according to the present invention showing the fifth embodiment.

FIG. 22 shows a bottom plan view of the ultrasonic vibrator set on the supporter 13 of the fifth embodiment shown in FIG. 21.

FIG. 23 shows a perspective view of the ultrasonic atomizing device of the fifth embodiment shown in FIG. 21.

FIG. 24 shows the characteristics of three types of ultrasonic vibrators shown in FIG. 21 on applied voltage, frequency, input power and current.

DETAILED DESCRIPTION OF THE INVENTION

Figure 1 shows a sectional view of the ultrasonic atomizing device according to the present invention showing the first embodiment. There is shown the ultrasonic atomizing device comprising a piezoelectric vibrator 1 to which a pair of electrode terminals, P and Q, made from copper ribbon are mounted, a vibrating plate 2, an assistance board 3, a clip 4, a liquid supplying tube 5, a flow control valve 6 and a liquid tank 7, and there is also shown therein a power supply circuit which supplies the piezoelectric vibrator 1 with an alternating current voltage. The liquid tank 7 is supplied with an adequate amount of liquid when using. The electrode terminals, P and Q, are cemented by an adhesive agent with high conductivity.

Figure 2 shows a sectional view of the first embodiment shown in FIG. 1 excepting the liquid supplying tube 5, the flow control valve 6 and the liquid tank 7. The ultrasonic vibrator composed of the piezoelectric vibrator 1 and the vibrating plate 2 is jointed to the assistance board 3 by the clip 4. The existence of the assistance board 3 is useful for the efficient transmission of the vibration of the piezoelectric vibrator 1 to the vibrating plate 2. The ultrasonic vibrator is maintained to have a slope of

about 30 degrees toward the surface of the liquid with a view to increase the speed of the liquid supply to the minute space between the vibrating plate 2 and the assistance board 3 and to atomize the liquid efficiently. The assistance board 3 is made from foamed styrene. Owing to adopting the material such as foamed styrene whose acoustic impedance is very low compared with the piezoelectric vibrator, the transmittance of the vibration of the piezoelectric vibrator to the assistance board is suppressed and the vibrating plate is vibrated efficiently, so that the atomization efficiency increases.

Figure 3 shows a perspective view of the clip 4 seen in FIG. 1. Figure 4 shows a side view of the clip 4 shown in FIG. 3. The clip 4 is made of stainless steel, and joins the piezoelectric vibrator 1 and the vibrating plate 2 together with the spring of the clip 4, so as to transmit the vibration of the piezoelectric vibrator 1 to the vibrating plate 2 efficiently, in other words to atomize the liquid efficiently.

The amount of the liquid drawn and guided by the flow control valve 6 from the liquid tank 7 through the liquid supplying tube 5 and then supplied into the minute space between the vibrating plate 2 and the assistance board 3 is controlled to make the atomization efficiency best. Thus, since the means for supplying the liquid comprises the liquid tank and the tube for drawing and guiding the liquid from the liquid tank and then supplying the vibrating plate with the liquid, the liquid is supplied efficiently on the vibrating plate without waste. Therefore the atomization efficiency can be enhanced.

Figure 5 shows a plan view of the ultrasonic vibrator (that is the device composed of the piezoelectric vibrator 1 and the vibrating plate 2) seen in FIG. 1. Figure 6 shows a fragmentary top plan view, on an enlarged scale, of a portion of the vibrating part 20 seen in FIG. 5. In FIG. 6 the shape, arrangement and size of a hole 22 are shown.

Figure 7 shows a side view of the ultrasonic vibrator shown in FIG. 5. The ultrasonic atomizing device can be made small and compact by incorporating a simple construction for the piezoelectric vibrator consisting of a piezoelectric ceramic and a pair of electrodes on the both end surfaces perpendicular to the polarization axis of the piezoelectric ceramic. In addition, it is possible to atomize a liquid with high efficiency and to operate the ultrasonic atomizing device under low power consumption.

Figure 8 shows a fragmentary vertical sectional view, on an enlarged scale, of a portion of the vibrating part 20 seen in FIG. 5. In FIG. 8 the shape and size of the hole 22 are shown.

The piezoelectric vibrator 1 has a rectangular plate-like piezoelectric ceramic 30, of which material is TDK-72A (Brand name), and of which dimension is 40 mm long, 20 mm wide and 1mm thick. As the TDK-72A has a large electromechanical coupling constant, the material has been utilized in the first embodiment of the invention. The direction of the polarization axis of the piezoelectric ceramic 30 is the same as that of thickness, and an Au electrode 31 and an Au electrode 32 are formed on the both end surfaces perpendicular to the direction of the thickness. The Au electrode 31 covers one end surface of the piezoelectric ceramic 30 and the Au electrode 32 covers the other end surface thereof. The Au electrode 31 is provided with an electrode terminal P, and the Au electrode 32 is provided with an electrode terminal Q. The electrode terminals, P and Q, are mounted at one edge along the direction of width of the piezoelectric ceramic 30.

The tongue-like vibrating plate 2 is attached to one end surface of the piezoelectric vibrator 1. The vibrating plate 2 is made of nickel and is cemented to be integrally interlocked with the piezoelectric vibrator 1 at a slender plate-like cemented part 21, thereby causing the vibrating plate 2. The part 21 is cemented to the piezoelectric vibrator 1 with an adhesive agent with high conductivity by way of the Au electrode 31. The dimension of the vibrating plate 2 is 25 mm long, 20 mm wide and 0.05mm thick. That of the cemented part 21 is 5 mm long, 20 mm wide and 0.05mm thick.

The vibrating part 20 extends in parallel with the plate surface of the piezoelectric vibrator 1 toward outside of the edge along the direction of the width of the piezoelectric vibrator 1 and is projected therefrom. The dimension of the vibrating part 20 is 20 mm long, 20 mm wide and 0.05mm thick. The vibrating part 20 is provided with plurality of minute holes 22 which are penetrated in the thickness direction. The holes 22 which are of inverse-conical shape and of which one opening area is larger than the other are utilized in the first embodiment. One opening is used as inlet side and the other is used as outlet side. The inlet side diameter is 0.1 mm and the outlet side diameter is 0.02 mm. The holes 22 are disposed with an equal pitch.

In case that the alternating current signal having almost the same frequency as the resonance frequency of the device composed of the piezoelectric vibrator 1 and the vibrating plate 2 is applied to the piezoelectric vibrator 1 through the electrode terminals, P and Q, when operating the ultrasonic atomizing device shown in FIG. 1, the piezoelectric vibrator 1 is vibrated. At this time, the frequency of the alternating current signal is almost agreed with one of the resonance frequencies of the piezoelectric vibrator 1. As such a construction

as the vibrating plate 2 is cemented to be integrally interlocked with at least one end surface of the piezoelectric vibrator 1 is employed, the vibrating plate 2 can vibrate just like a one-side supported overhanging beam with the cemented part 21 acted as an cementing end. A liquid which is supplied the vibrating part 20 under a strong acoustic vibrating condition can be atomized or sprayed upwards in the vertical direction. Furthermore, as the atomizing quantity can be increased in the case that the applied voltage is increased, it is possible to change the atomizing quantity by changing the applied voltage according to a purpose.

In the ultrasonic atomizing device shown in FIG. 1, the liquid which is supplied into the minute space through the liquid supplying tube 5 from the liquid tank 7 in accompanying with the vibration of the vibrating part 2 is led to the respective holes 22 by capillarity. When the liquid passes through each of the holes 22, the passing area of liquid in each of the holes 22 is reduced from the inlet side thereof to the outlet side thereof. Therefore, the liquid is squeezed out by the respective holes 22, thereby causing the liquid to become minute and uniform particles and to flow out on the vibrating part 20. Consequently the liquid which flows out from the respective holes 22 can be atomized very effectively by virtue of the above squeezing action, the acoustic vibration of the vibrating part 20, the increase action of liquid feeding speed by that the ultrasonic vibrator makes an angle from the horizontality, and the liquid limiting action into the above minute space by the flow control valve 6.

Figure 9 shows the frequency dependences of the magnitude and the phase of the admittance of the piezoelectric vibrator 1. One of the frequencies which can effectively operate as an atomizing device is such as can correspond to resonance around 100.8 kHz.

Figure 10 shows the relationship between the atomizing quantity and the applied voltage for the first embodiment. As the applied voltage becomes more 0 ~ 30 Vp-p or more, fog can be blown out from the vibrating part 20. At the resonance frequency 100.8 kHz, the applied voltage which can produce the maximum atomizing quantity is 76 Vp-p. With the voltage more than 76 Vp-p, the atomizing quantity is saturated. As shown in FIG. 10, the atomizing quantity is radically increased according to the applied voltage up to around 60 Vp-p.

Figure 11 shows the relationship between the atomizing height and the atomizing distance for various applied voltages for the first embodiment. FIG. 11 shows changes similar to those in FIG. 10, the power of fog is strengthened radically from around 40 Vp-p and is saturated at 60 Vp-p.

Figure 12 shows a plan view of the ultrasonic vibrator taking the place of that shown in FIG. 5. In

FIG. 12 the ultrasonic vibrator has the piezoelectric vibrator 1 of which size is 22 mm long, 20 mm wide and 1 mm thick and the vibrating plate 2 having the vibrating part 20 of which size is 17 mm long, 20 mm wide and 0.05 mm thick. In the case that the ultrasonic vibrator in FIG. 12 is used, the atomizing quantity becomes the maximum with the frequency of 114.6 kHz when the applied voltage is 9.8 V. Then, the power consumption is 294 mW and the current is 30 mA. As for the whole atomizing device including a power supply, the power consumption is 588 mW and the current is 60 mA. Thus, in the case that such a rectangular plate-like structure as the proportion with the length and the width is nearly 1 but is not equal to 1 as piezoelectric vibrator is employed, the coupled-mode vibration of the device composed of the piezoelectric vibrator and the vibrating plate is strengthened, and the atomizing quantity is further increased.

Figure 13 shows the relationship between the length of the vibrating part 20 and the atomizing quantity for the ultrasonic vibrator shown in FIG. 12. When the length of the vibrating part 20 is 17 mm, the atomizing quantity shows the maximum value of 27.5 ml/min. Figure 14 shows the relationship between the length of the vibrating part 20 shown in FIG. 12 and the atomizing height. However, at this time, the atomizing height is what the oblique spouting is converted to the value in the upright direction. When the length of the vibrating plate 20 is 17 mm, the atomizing height reaches the maximum value of 112 cm.

Figure 15 shows the relationship between the phase of the impedance of the piezoelectric vibrator 1 seen in FIG. 12 and the frequency. Figure 16 shows the relationship between the phase of the impedance of the device composed of the piezoelectric vibrator 1 and the vibrating plate 2 shown in FIG. 12 and the frequency. With the phase set to zero degree, the value of the frequency shows the resonance frequency. Therefore, in FIG. 15, the piezoelectric vibrator 1 has four resonance frequencies. fa shows the intermediate value of the two resonance frequencies of the four resonance frequencies. In FIG. 16, the peak around fa is separated into two, causing the resonance frequencies fb1 and fb2 to be generated. The intermediate value fo thereof shows the frequency when the atomizing quantity becomes the maximum, and the fo is almost equivalent to the fa. Thus, by employing such a structure as the intermediate value of the two resonance frequencies of the device composed of the piezoelectric vibrator and the vibrating plate becomes almost equivalent to the resonance frequency of the single piezoelectric vibrator, the coupled-mode vibration of the device composed of the piezoelectric vibrator and the vibrating plate is strengthened. Therefore, the atomizing quantity can

be further increased. Furthermore, the fb1 and the fb2 is deviated toward the higher frequency side as the length of the vibrating part 20 is shortened. As the vibrating part becomes far from the fa, the atomizing quantity is decreased.

Figure 17(A) shows a perspective view of the ultrasonic vibrator taking the place of that shown in FIG. 5. In FIG. 17(A) the ultrasonic vibrator has the piezoelectric vibrator 41 of which size is 20 mm long, 5 mm wide and 6 mm thick and the vibrating plate 46 having the vibrating part 47 of which size is 10.5 mm long, 5 mm wide and 0.04 mm thick and the cemented part 48 of which size is 1.5 mm long, 5 mm wide and 0.04 mm thick. Au electrodes, 43, 44 and 45 are formed on the both end surfaces perpendicular to the direction of the polarization axis of a piezoelectric ceramic 42. The electrodes 43 and 44 are mounted on the same surface and insulated each other. The electrode 43 covers the part of 15mm long from the distal end of the piezoelectric ceramic 42 in the length direction thereof and is used as the electrode for applying the alternating current voltage to the piezoelectric vibrator 41. The electrode 44 covers the remaining part apart by 1mm from the electrode 43 and is used as the electrode for self-exciting power supply. In the case that the ultrasonic vibrator in FIG. 17(A) is employed, it has been confirmed that the atomizing quantity becomes the maximum with the frequency of about 100 kHz and the fog particles are minute and uniform. Thus, in the case that such a rectangular prism-like structure as the proportion with the thickness and the width is nearly 1 but is not equal to 1 as the piezoelectric vibrator is employed, the coupled-mode vibration of the device composed of the piezoelectric vibrator and the vibrating plate is strengthened, and the atomizing quantity can be further increased. By employing two electrodes, which are insulated from each other, on one end surface perpendicular to the polarization axis of the piezoelectric ceramic, one of the electrodes can be used as the electrode for self-exciting power supply. It is therefore possible to provide the stabilized and very efficient ultrasonic atomizing device which is operated with a low power consumption.

Figure 17(B) shows a perspective view of the ultrasonic vibrator taking the place of that shown in FIG. 17(A). In FIG. 17(B) the ultrasonic vibrator has the piezoelectric vibrator 41 of which size is 10 mm long, 5 mm wide and 6 mm thick and the vibrating plate 46 of which size is 11 mm long, 5 mm wide and 0.04 mm thick. The vibrating plate 46 is mounted under the piezoelectric vibrator 41 unlike the ultrasonic vibrator in FIG. 17(A). In the case that the ultrasonic vibrator in FIG. 17(B) is employed, it is possible, like the ultrasonic vibrator in FIG. 17(A), to provide the stabilized and very efficient

ultrasonic atomizing device which is operated with a low power consumption.

Figure 18 shows a sectional view of the ultrasonic atomizing device, showing the second embodiment, excluding the liquid supplying tube 5, the flow control valve 6 and the liquid tank 7 from the first embodiment shown in FIG. 1 and including the liquid bath 8 in the first embodiment in FIG. 1. The liquid bath 8 is supplied with an adequate amount of liquid when using. The ultrasonic vibrator composed of the piezoelectric vibrator 1 and the vibrating plate 2 is jointed to the assistance board 3 by the clip 4 and only the distal end of the vibrating plate 2 is in touch with the liquid level with an angle of 30 degrees to the horizontality. This is used for limiting the amount of liquid which comes in touch with the vibrating plate 2 and is for effective atomizing. In the case that the ultrasonic vibrator further comes in touch with the liquid than the necessity, almost all the energy of the ultrasonic vibration is discharged in the liquid, thereby causing the atomization efficiency to be lowered.

In case that the alternating current signal having almost the same frequency as the resonance frequency of the device composed of the piezoelectric vibrator 1 and the vibrating plate 2 is applied to the piezoelectric vibrator 1 through the electrode terminals, P and Q, when operating the ultrasonic atomizing device shown in FIG. 18, the piezoelectric vibrator 1 is vibrated. At this time, the frequency of the alternating current signal is almost agreed with one of the resonance frequencies of the piezoelectric vibrator 1. As such a construction as the vibrating plate 2 is cemented to be integrally interlocked with at least one end surface of the piezoelectric vibrator 1 is employed, the vibrating plate 2 can vibrate just like a one-side supported overhanging beam with the cemented part 21 acted as an cementing end. A liquid which is supplied the vibrating part 20 under a strong acoustic vibrating condition can be atomized or sprayed upwards in the vertical direction.

In the ultrasonic atomizing device shown in FIG. 18, the liquid which is supplied in the liquid bath 8 in accompanying with the vibration of the vibrating part 2 is led to the respective holes 22 by capillarity. When the liquid passes through each of the holes 22, the passing area of liquid in each of the holes 22 is reduced from the inlet side thereof to the outlet side thereof. Therefore, the liquid is squeezed out by the respective holes 22, thereby causing the liquid to become minute and uniform particles and to flow out on the vibrating part 20. Consequently the liquid which flows out from the respective holes 22 can be atomized very effectively by virtue of the above squeezing action, the acoustic vibration of the vibrating part 20, and the liquid limiting action by use of the assistance board

3.

Figure 19 shows a sectional view of the ultrasonic atomizing device, showing the third embodiment, excluding the assistance board 3 and the clip 4 from the first embodiment shown in FIG. 1 and setting the liquid supplying tube 5 upward the vibrating plate 2. When using, the liquid flow rate is controlled by the flow control valve 6 from the liquid tank 7 and the liquid is caused to drop on the surface of the vibrating plate 2, passing through the liquid supplying tube 5. According to the liquid dropping means, the liquid amount which comes in touch with the vibrating plate 2 can be controlled, and it is possible to supply the liquid amount at which the atomization efficiency becomes the highest.

In case that the alternating current signal having almost the same frequency as the resonance frequency of the device composed of the piezoelectric vibrator 1 and the vibrating plate 2 is applied to the piezoelectric vibrator 1 through the electrode terminals, P and Q, when operating the ultrasonic atomizing device shown in FIG. 19, the piezoelectric vibrator 1 is vibrated. At this time, the frequency of the alternating current signal is almost agreed with one of the resonance frequencies of the piezoelectric vibrator 1. As such a construction as the vibrating plate 2 is cemented to be integrally interlocked with at least one end surface of the piezoelectric vibrator 1 is employed, the vibrating plate 2 can vibrate just like a one-side supported overhanging beam with the cemented part 21 acted as an cementing end. A liquid which is supplied the vibrating part 20 under a strong acoustic vibrating condition can be atomized or sprayed upwards in the vertical direction.

In the ultrasonic atomizing device shown in FIG. 19, the liquid which is caused to drop on the surface of the vibrating plate 2, passing through the liquid supplying tube 5 from the liquid tank 7, is efficiently atomized by the acoustic vibration of the vibrating part 20, the effects of the holes 22, and the liquid amount limiting action on the surface of the vibrating part 20 by use of a dropping structure.

Figure 20 shows a sectional view of the ultrasonic atomizing device according to the present invention showing the fourth embodiment. There is shown the ultrasonic atomizing device comprising the piezoelectric vibrator 1, the vibrating plate 2, which are used in the first embodiment in FIG. 1, the liquid bath 8, which is used in the second embodiment in FIG. 18, the supporter 9 and the liquid keeper 10. There is also shown therein a power supply circuit which supplies the piezoelectric vibrator 1 with an alternating current voltage. The liquid bath 8 is supplied with an adequate amount of liquid when using. The electrode termi-

The ultrasonic vibrator composed of the piezo-electric vibrator 11 and the vibrating plate 12 is jointed to the assistance board 13, and is floated on the liquid by the floating force when using. At this time, the assistance board 13 intercepts the piezoelectric vibrator 11 from the liquid and prevents the energy of the ultrasonic vibration from being discharged into the liquid. Therefore, the energy can be effectively transmitted to the vibrating plate 12. Owing to adopting the material, as the assistance board, such as foamed styrene whose acoustic impedance is very low compared with the piezoelectric vibrator, the transmittance of the vibration of the piezoelectric vibrator to the assistance board is suppressed and the piezoelectric vibrator is vibrated efficiently, so that the atomization efficiency is increased. By employing such a structure that the ultrasonic atomizing device is floated on the liquid by virtue of floating force, an adequate amount of liquid is supplied to the vibrating plate at all times without being influenced by the increase or decrease of the liquid in the liquid bath. So, efficient atomizing can be realized. Therefore, a great deal of atomizing can be realized with only a low power consumption. In addition, it is easily possible to make the device small and compact. Still furthermore, efficient atomizing is realized by supplying an adequate amount of liquid to the vibrating part with the ultrasonic vibrator held

In the ultrasonic atomizing device shown in FIG. 20, the liquid in the liquid bath 8 can be lifted up by the liquid keeper 10 and reaches the underside of the vibrating plate 2. The liquid is led to the respective holes 22 by capillarity in accompanying with the vibration of the vibrating part 2. When the liquid passes through each of the holes 22, the passing area of liquid in each of the holes 22 is reduced from the inlet side thereof to the outlet side thereof. Therefore, the liquid is squeezed out by the respective holes 22, thereby causing the liquid to become minute and uniform particles and to flow out on the vibrating part 20. Consequently the liquid which flows out from the respective holes 22 is atomized very effectively by virtue of the above squeezing action, the acoustic vibration of the vibrating part 20.

at an appointed position for the fixing substance by means of the assistance board.

Figure 22 shows a bottom plan view of the ultrasonic vibrator set on the supporter 13 of the fifth embodiment shown in FIG. 21. Figure 23 shows a perspective view of the ultrasonic atomizing device of the fifth embodiment shown in FIG. 21. The piezoelectric vibrator 11 has a column-like piezoelectric ceramic 60 having a hole which is penetrated through parallel to the polarization axis with the faces thereof vertical to the polarization axis used as end surface, respectively. The material of the piezoelectric ceramic 60 is TDK-72A (Brand name), and the dimension thereof is 24 mm diameter and 6 mm thick. The hole is also column-like with 12 mm thickness. As the TDK-72A has a large electromechanical coupling constant, the material has been utilized in the fifth embodiment of the invention. An Au electrode 31 and an Au electrode 32 are formed on the end surface, respectively. The Au electrode 31 is provided with an electrode terminal P, and the Au electrode 32 is provided with an electrode terminal Q.

A disk-like vibrating plate 12 is mounted to the position which covers the opening of the penetrated hole at the underside end surface of the piezoelectric vibrator 11. The vibrating plate 12 is made of nickel and is fixed to be integrally interlocked with the piezoelectric vibrator 11 by a ring-like cemented part 51, and the vibrating plate 12 surrounded by the cemented part 51 forms the vibrating part 50. The cemented part 51 is cemented to the piezoelectric vibrator 11 with an adhesive agent with high conductivity by way of the Au electrode 62. The diameter of the vibrating plate 12 is 14 mm and the thickness thereof is 0.05 mm. The diameter of the vibrating part 50 is agreed with that of the penetrated hole and is 12 mm. And the thickness is 0.05 mm. The vibrating part 50 is provided with a plurality of minute holes which are penetrated in the thickness direction, and the dimension and shape thereof are the same as those of the holes 22 in FIG. 6 and FIG. 8. Thus, by employing the ring-like structure as the piezoelectric ceramic, in which the hole is penetrated through parallel to the polarization axis thereof, and employing such a structure that the vibrating plate is mounted, almost parallel to the end faces, on the position which covers the opening of the penetrated hole at the underside end surface of the piezoelectric vibrator or the inside of the penetrated hole, the vibrating plate is vibrated efficiently, so that the atomization efficiency is increased.

In case that the alternating current signal having almost the same frequency as the resonance frequency of the device composed of the piezoelectric vibrator 11 and the vibrating plate 12 is applied to the piezoelectric vibrator 11 through the

electrode terminals, P and Q, when operating the ultrasonic atomizing device shown in FIG. 21, the piezoelectric vibrator 11 is vibrated. At this time, the vibrating part 50 which is surrounded by the ring-like cemented part 51 makes the coupled-mode vibration integrally together with the piezoelectric vibrator 11. Thus, by employing such a structure that the vibrating plate is mounted on the position which covers the opening of the penetrated hole of the piezoelectric vibrator to link together as one body, and a structure that one of the resonance frequencies of the device composed of the piezoelectric vibrator and the vibrating plate is almost agreed with one of the resonance frequencies of the piezoelectric vibrator, the vibrating part 50 makes the coupled-mode vibration integrally together with the piezoelectric vibrator 11. The coupled-mode vibration of the vibrating part 50 acts very effectively for atomizing the liquid. The liquid which is supplied in the liquid bath 8 in accompanying with the vibration of the vibrating part 50 is led to the respective holes 22 by capillarity. When the liquid passes through each of the holes 22, the passing area of liquid in each of the holes 22 is reduced from the inlet side thereof to the outlet side thereof. Therefore, the liquid is squeezed out by the respective holes 22, thereby causing the liquid to become minute and uniform particles and to flow out on the vibrating part 50. Consequently the liquid which flows out from the respective holes 22 can be atomized very effectively by virtue of the above squeezing action, the coupled-mode vibration of the vibrating part 50, and the effect that the assistance board covers the piezoelectric vibrator to prevent the liquid coming in touch with the piezoelectric vibrator.

Figure 24 shows the characteristics of three types of ultrasonic vibrators shown in FIG. 21 on applied voltage, frequency, input power and current. In the types I and II, the vibrating plate is mounted on the underside of the piezoelectric vibrator. In the type III in which the device composed of the piezoelectric vibrator and the vibrating plate has the same dimensions as that of the type II, the vibrating plate is mounted on the upperside of the piezoelectric vibrator. The type II is the device composed of the piezoelectric vibrator 11 and the vibrating plate 12 shown in FIG. 21. In the case that the type II is used, the atomizing quantity becomes the maximum with the frequency of 290.6 kHz when the applied voltage is 10.7 V. Then, the input power is 320 mW and the current is 30 mA. As for the whole atomizing device including the power supply, the input power is 642 mW and the current is 60 mA. Thus, in the case that such a ring-like structure as the ratio between the length in the direction of the polarization axis of the piezoelectric vibrator and the shortest distance of the outer edge

and the inner edge of the end surface is approximately equal to 1 is employed, the coupled-mode vibration of the device composed of the piezoelectric vibrator and the vibrating plate can be strengthened, and the atomizing quantity can be further increased. In the case that the type II has another vibrating plate having the same structure as that of the type II on the upperside of the piezoelectric vibrator, in other words, the type II has the two vibrating plates, it has been confirmed that the atomizing quantity is decreased with the characteristics of the type II remained unchanged, but remarkably minute fog particles can be effectively generated. Thus, in the case that a plurality of vibrating plates are utilized, the minuteness of fog particle can be more promoted.

While certain preferred features of the invention have been shown by way of illustration, many modifications and changes will occur to those skilled in the art. It is therefore, to be understood that the appended claims are intended to cover all such modifications and changes as fall within the true spirit of the invention.

Claims

1. An ultrasonic device for atomizing a liquid by the acoustic vibration generated with a vibrating plate being mounted to a piezoelectric vibrator, comprising;
a means for supplying said vibrating plate with said liquid,
said vibrating plate having a lot of holes,
said piezoelectric vibrator consisting of a piezoelectric ceramic and a pair of electrodes on the both end surfaces perpendicular to the thickness direction of said piezoelectric ceramic.
2. A device as defined in claim 1, wherein the area of the one of the openings of said hole on said vibrating plate is different from the area of the other.
3. A device as defined in claim 1 or 2, wherein said vibrating plate is mounted at least on one of said end surfaces having said electrodes of said piezoelectric vibrator to link together as one body and has a vibrating part prominent in parallel approximately to said end surface of said piezoelectric vibrator for the outside of said piezoelectric vibrator, and said hole is formed in said vibrating part,
4. A device as defined in claim 1, 2 or 3, wherein the resonance frequency of said piezoelectric vibrator is approximately equal to the mediate value of two resonance frequencies of the

complex of said piezoelectric vibrator and said vibrating plate.

5. A device as defined in claim 4, wherein said piezoelectric vibrator is a rectangular board in which the proportion with the length and the width is nearly but not equal to 1.
6. A device as defined in claim 4, wherein said piezoelectric vibrator is in the rectangular form in which the proportion with the thickness and the width is nearly but not equal to 1.
7. A device as defined in claim 6, wherein the electrode on only said end surface is divided into two parts insulated each other.
8. A device as defined in claim 1 or 2, wherein said piezoelectric ceramic has a pierced hole which is passed through in parallel to a polarization axis of said piezoelectric ceramic, said vibrating plate which covers the opening of said pierced hole in parallel with said end surface perpendicular to said polarization axis, is mounted at least more than one part of said pierced hole corresponding to the inside of the piezoelectric ceramic, the flange of said vibrating plate is stuck with said piezoelectric vibrator, the part which is surrounded by a cemented part stuck with said piezoelectric vibrator operates as a vibrating part, and said holes are formed in said vibrating part.
9. A device as defined in claim 8, wherein one of the resonance frequencies of said piezoelectric vibrator is approximately equal to one of the resonance frequencies of the complex of said piezoelectric vibrator and said vibrating plate.
10. A device as defined in claim 8 or 9, wherein said piezoelectric vibrator is like a rectangle or a circle, and the ratio between the length in the direction of the polarization axis of said piezoelectric vibrator and the shortest distance of the outer edge and the inner edge of said end surface is approximately equal to 1.
11. A device as defined in claim 1 to 7, wherein said means for supplying said vibrating plate with said liquid comprises a supporting board parallel to said vibrating plate via a minute gap from said vibrating plate, a means for maintaining the fixed position of said ultrasonic vibrator and said supporting board to a liquid bath accommodating a liquid, said means for maintaining the fixed position making said vibrating plate incline toward the surface of said liquid and also making the position of said vibrating

plate on the upper side over said supporting board, said supporting board being made from foamed styrene and others whose acoustic impedance is low compared with a piezoelectric vibrator.

5

12. A device as defined in claim 1, 2, 8, 9 or 10, wherein said means for supplying said vibrating plate with said liquid comprises a supporting board for supporting said piezoelectric vibrator, a liquid bath for accommodating a liquid, said supporting board maintaining said ultrasonic vibrator at a fixed position or making said ultrasonic vibrator float in said liquid with buoyancy, said supporting board being made from foamed styrene and others whose acoustic impedance is low compared with a piezoelectric vibrator.
13. A device as defined in claim 1 to 12, wherein said means for supplying said vibrating plate with said liquid comprises a liquid tank and a tube for supplying said vibrating plate with said liquid from said liquid tank.
14. A device as defined in claim 1 to 12, wherein said means for supplying said vibrating plate with said liquid comprises a liquid tank and a means for drawing and guiding said liquid from said liquid tank and dropping said liquid on said vibrating plate.
15. A device as defined in claim 1 to 12, wherein said means for supplying said vibrating plate with said liquid comprises a liquid-storage material made from sponge and other material with a large absorption ability, and a liquid bath accommodating said liquid-storage material.
